## Introduction

Hello!

This is a book about IDAPython.

I originally wrote it as a reference for myself - I wanted a place to go to where I could find

examples of functions that I commonly use (and forget) in IDAPython. Since I started this book I have used it many times as a quick reference to understand syntax or see an example of some code - if you follow my blog you may notice a few familiar faces – lots of scripts that I cover here are result of sophomoric experiments that I documented online.

Over the years I have received numerous emails asking what is the best guide for learning IDAPython. Usually I will point them to to Ero Carrera's *Introduction to IDAPython* or the example scripts in the IDAPython's public repo. They are excellent sources for learning but they don't cover some common issues that I have come across. I wanted to create a book that covers these issues. I feel this book will be of value for anyone learning IDAPython or wanting a quick reference for examples and snippets. Being an e-book it will not be a static document and I plan on updating it in the future on regular basis.

If you come across any issues, typos or have questions please send me an email **alexander< dot >hanel< at >gmail< dot > com**.

## Updates

Version 1.0 - Published

Version 2.0 - Table of Contents and closing added

## Intended Audience & Disclaimer

This book is not intended for beginner reverse engineers. It is also not to serve as an introduction to IDA. If you are new to IDA, I would recommend purchasing Chris Eagles' *The IDA PRO Book*. It is an excellent book and is worth every penny.

There are a couple of prerequisites for purchasers of this book. You should be comfortable with reading assembly, a background in reverse engineering and know your way around IDA. If you have hit a point where you have asked yourself "How can I automate this task using IDAPython?" then this book might be for you. If you already have a handful of programming in IDAPython under your belt then odds are this book is not for you. This book is for beginners of IDAPython. It will serve as a handy reference to find examples of commonly used functions but odds are you already have your own references of one off scripts.

It should be stated that my background is in reverse engineering of malware. This book

does not cover compiler concepts such as basic blocks or other academic concepts used in static analysis. The reason be, is I rarely ever use these concepts when reverse engineering malware. Occasionally I have used them for de-obfuscating code but not often enough that I feel they would be of value for a beginner. After reading this book the reader will feel comfortable with digging into the IDAPython documentation on their own. One last disclaimer, functions for IDA's debugger are not covered.

## Conventions

IDA's Output Windows (command line interface) was used for the examples and output. For brevity some examples do not contain the assignment of the current address to a variable. Usually represented as `ea = here()`. All of the code can be cut and paste into the command line or IDA's script command option `shift-F2`. Reading from beginning to end is the recommend approach for this book. There are a number of examples that are not explained line by line because it assumed the reader understands the code from previous examples. Different authors will call IDAPython's in different ways. Sometimes the code will be called as `idc.SegName(ea)` or `SegName(ea)`. In this book we will be using the first style. I have found this convention to be easier to read and debug. Sometimes when using this convention an error will be thrown as shown below.

```
Python>DataRefsTo(here())
<generator object refs at 0x05247828>
Python>idautils.DataRefsTo(here())
Traceback (most recent call last):
  File "<string>", line 1, in <module>
NameError: name 'idautils' is not defined
Python>import idautils # manual importing of module
Python>idautils.DataRefsTo(here())
<generator object refs at 0x06A398C8>
```

If this happens the module will be need to be manually imported as shown above.

## IDAPython Background

IDAPython was created in 2004. It was a joint effort by Gergely Erdelyi and Ero Carrera. Their goal was to combine the power of Python with the analysis automation of IDA's IDC C-like

scripting language. IDAPython consists of three separate modules. The first is `idc`. It is a compatibility module for wrapping IDA's IDC functions. The second module is `idautils`. It is a high level utility functions for IDA. The third module is `idaapi`. It allows access to more low level data. This data could be classes used by IDA.

## Basics

Before we dig too deep we should define some keywords and go over the structure of IDA's disassembly output. We can use the following line of code as an example.

```
.text:00012529          mov     esi, [esp+4+arg_0]
```

The `.text` is the section name and the address is `00012529`. The displayed address is in a hexadecimal format. The instruction `mov` is referred to as a mnemonic. After the mnemonic is the first operand `esi` and the second operand is `[esp+4+arg_0]`. When working with IDAPython functions the most common passed variable is the address. In the IDAPython documentation the address is referenced as `ea`. The address can be accessed manually by a couple of different functions. The most commonly used functions are `idc.ScreenEA()` or `here()`. They will return an integer value. If we want to get the minimum address that is present in an IDB we can use `MinEA()` or to get the max we can use `MaxEA()`.

```
Python>ea = idc.ScreenEA()
Python>print "0x%x %s" % (ea, ea)
0x12529 75049
Python>ea = here()
Python>print "0x%x %s" % (ea, ea)
0x12529 75049
Python>hex(MinEA())
0x401000
Python>hex(MaxEA())
0x437000
```

Each described element in the disassembly output can be accessed by a function in IDAPython. Below is an example of how to access each element. Please recall that we previously stored the address in `ea`.

```
Python>idc.SegName(ea) # get text
```

```
.text
Python>idc.GetDisasm(ea) # get disassembly
mov     esi, [esp+4+arg_0]
Python>idc.GetMnem(ea) # get mnemonic
mov
Python>idc.GetOpnd(ea,0) # get first operand
esi
Python>idc.GetOpnd(ea,1) # get second operand
[esp+4+arg_0]
```

To get a string representation of the segments name we would use `idc.SegName(ea)` with `ea` being an address within the segment. Printing a string of the disassembly can be done with `idc.GetDisasm(ea)`. It's worth noting the spelling of the function. To get the mnemonic or the instruction name we would call `idc.GetMnem(ea)`. To get the operands of the mnemonic we would call `idc.GetOpnd(ea, long n)`. The first argument is the address and the second `long n` is the operand index. The first operand is 0 and the second is 1.

In some situations it will be important to verify an address exists. `idaapi.BADADDR` or `BADADDR` can be used to check for valid addresses.

```
Python>idaapi.BADADDR
4294967295
Python>hex(idaapi.BADADDR)
0xffffffffL
Python>if BADADDR != here(): print "valid address"
valid address
```

## Segments

Printing a single line is not very useful. The power of IDAPython comes from iterating through all instructions, cross-references addresses and searching for code or data. The last two will be described in more details later. Iterating through all segments will be a good place to start.

```
Python>for seg in idutils.Segments():
    print idc.SegName(seg), idc.SegStart(seg), idc.SegEnd(seg)
HEADER 65536 66208
.idata 66208 66636
```

```
.text 66636 212000
.data 212000 217088
.edata 217088 217184
INIT 217184 219872
.reloc 219872 225696
GAP 225696 229376
```

`idautils.Segments()` returns an iterator type object. We can loop through the object by using a for loop. Each item in the list is a segment's start address. The address can be used to get the name if we pass it as an argument to `idc.SegName(ea)`. The start and end of the segments can be found by calling `idc.SegStart(ea)` or `idc.SegEnd(ea)`. The address or `ea` needs to be within the range of the start or end of the segment. If we didn't want to iterate through all segments but wanted to find the next segment we could use `idc.NextSeg(ea)`. The address can be any address within the segment range for which we would want to find the next segment for. If by chance we wanted to get a segment's start address by name we could use `idc.SegByName(segname)`.

## Functions

Now that we know how to iterate through all segments we should go over how to iterate through all known functions.

```
Python>for func in idautils.Functions():
    print hex(func), idc.GetFunctionName(func)
Python>
0x401000 ?DefWindowProcA@CWnd@@MAEJIIJ@Z
0x401006 ?
LoadFrame@CFrameWnd@@UAEHKPAVCWnd@@PAUCCreateContext@@@Z
0x40100c ??2@YAPAXI@Z
0x401020 save_xored
0x401030 sub_401030
....
0x45c7b9 sub_45C7B9
0x45c7c3 sub_45C7C3
0x45c7cd SEH_44A590
0x45c7e0 unknown_libname_14
0x45c7ea SEH_43EE30
```

`idautils.Functions()` will return a list of known functions. The list will contain the start

address of each function. `idautils.Functions()` can be passed arguments to search within a range. If we wanted to do this we would pass the start and end address `idautils.Functions(start_addr, end_addr)`. To get a functions name we use `idc.GetFunctionName(ea)`. `ea` can be any address within the function boundaries. IDAPython contains a large set of APIs for working with functions. Let's start with a simple function. The semantics of this function is not important but we should create a mental note of the addresses.

```
.text:0045C7C3 sub_45C7C3      proc near
.text:0045C7C3                mov     eax, [ebp-60h]
.text:0045C7C6                push   eax                ; void *
.text:0045C7C7                call  w_delete
.text:0045C7CC                retn
.text:0045C7CC sub_45C7C3      endp
```

To get the boundaries we can use `idaapi.get_func(ea)`.

```
Python>func = idaapi.get_func(ea)
Python>type(func)
<class 'idaapi.func_t'>
Python>print "Start: 0x%x, End: 0x%x" % (func.startEA,
func.endEA)
Start: 0x45c7c3, End: 0x45c7cd
```

`idaapi.get_func(ea)` returns a class of `idaapi.func_t`. Sometimes it is not always obvious how to use a class returned by a function call. A useful command to explore classes in Python is the `dir(class)` function.

```
Python>dir(func)
['__class__', '__del__', '__delattr__', '__dict__', '__doc__',
'__eq__', '__format__', '__getattr__', '__gt__',
'__hash__', '__init__', '__lt__', '__module__', '__ne__',
'__new__', '__reduce__', '__reduce_ex__', '__repr__',
'__setattr__', '__sizeof__', '__str__', '__subclasshook__',
'__swig_destroy__', '__weakref__', '_print', 'analyzed_sp',
'argsize', 'clear', 'color', 'compare', 'contains', 'does_return',
'empty', 'endEA', 'extend', 'flags', 'fpd', 'frame', 'frregs',
'frsize', 'intersect', 'is_far', 'llabelqty', 'llabels',
'overlaps', 'owner', 'pntqty', 'points', 'referers', 'refqty',
'regargqty', 'regargs', 'regvarqty', 'regvars', 'size', 'startEA',
'tailqty', 'tails', 'this', 'thisown']
```

From the output we can see the `startEA` and `endEA` this is used to access the start and end of the function. These attributes are only applicable towards the current function. If we wanted to access surrounding functions we could use `idc.NextFunction(ea)` and `idc.PrevFunction(ea)`. The value of `ea` only needs to be an address within the boundaries of the analyzed function. A caveat with enumerating functions is that it only works if IDA has identified the block of code as a function. Until the block of code is marked as a function it will be skipped during the function enumeration process. Code that is not marked as functions will be labeled red in the legend (colored bar at the top). These can be manually fixed or automated.

IDAPython has a lot of different ways to access the same data. A common approach for accessing the boundaries within a function is using `idc.GetFunctionAttr(ea, FUNCATTR_START)` and `idc.GetFunctionAttr(ea, FUNCATTR_END)`.

```
Python>ea = here()
Python>start = idc.GetFunctionAttr(ea, FUNCATTR_START)
Python>end = idc.GetFunctionAttr(ea, FUNCATTR_END)
Python>cur_addr = start
Python>while cur_addr <= end:
    print hex(cur_addr), idc.GetDisasm(cur_addr)
    cur_addr = idc.NextHead(cur_addr, end)
Python>
0x45c7c3 mov     eax, [ebp-60h]
0x45c7c6 push    eax           ; void *
0x45c7c7 call    w_delete
0x45c7cc retn
```

`idc.GetFunctionAttr(ea, attr)` is used to get the start and end of the function. We then print the current address and the disassembly by using `idc.GetDisasm(ea)`. We use `idc.NextHead(eax)` to get the start of the next instruction and continue until we reach the end of this function. A flaw to this approach is it relies on the instructions to be contained within the boundaries of the start and end of the function. If there was a jump to an address higher than the end of the function the loop would prematurely exit. These types of jumps are quite common in obfuscation techniques such as code transformation. Since boundaries can be unreliable it is best practice to call `idautils.FuncItems(ea)` to loop through addresses in a function. We will go into more details about this approach in the following section.

Similar to `idc.GetFunctionAttr(ea, attr)` another useful function for gathering information about functions is `GetFunctionFlags(ea)`. It can be used to retrieve information about a function such as if it's library code or if the function doesn't return a value. There are nine possible flags for a function. If we wanted to enumerate all the flags for all the functions we could use the following code.

```

Python>import idutils
Python>for func in idutils.Functions():
    flags = idc.GetFunctionFlags(func)
    if flags & FUNC_NORET:
        print hex(func), "FUNC_NORET"
    if flags & FUNC_FAR:
        print hex(func), "FUNC_FAR"
    if flags & FUNC_LIB:
        print hex(func), "FUNC_LIB"
    if flags & FUNC_STATIC:
        print hex(func), "FUNC_STATIC"
    if flags & FUNC_FRAME:
        print hex(func), "FUNC_FRAME"
    if flags & FUNC_USERFAR:
        print hex(func), "FUNC_USERFAR"
    if flags & FUNC_HIDDEN:
        print hex(func), "FUNC_HIDDEN"
    if flags & FUNC_THUNK:
        print hex(func), "FUNC_THUNK"
    if flags & FUNC_LIB:
        print hex(func), "FUNC_BOTTOMBP"

```

We use `idutils.Functions()` to get a list of all known functions addresses and then we use `idc.GetFunctionFlags(ea)` to get the flags. We check the value by using a logical `&` on the returned value. For example to check if the function does not have a return value we would use the following comparison `if flags & FUNC_NORET`. Now lets go over all the flags. Some of these flags are very common while the other are rare.

## FUNC\_NORET

This flag is used to identify a function that does not execute a return instruction. It's internally represented as equal to 1. An example of a function that does not return a value can be seen below.

```

CODE:004028F8 sub_4028F8      proc near
CODE:004028F8
CODE:004028F8      and     eax, 7Fh
CODE:004028FB      mov     edx, [esp+0]
CODE:004028FE      jmp     sub_4028AC
CODE:004028FE sub_4028F8      endp

```

Notice how `ret` or `leave` is not the last instruction.

## FUNC\_FAR

This flag is rarely seen unless reversing software that uses segmented memory. It is internally represented as an integer of 2.

## FUNC\_USERFAR

This flag is rarely seen and has very little documentation. HexRays describes the flag as “user has specified far-ness of the function”. It has an internal value of 32.

## FUNC\_LIB

This flag is used to find library code. Identifying library code is very useful because it is code that typically can be ignored when doing analysis. It's internally represented as an integer value of 4. Below is an example of its usage and functions it has identified.

```
Python>for func in idutils.Functions():
    flags = idc.GetFunctionFlags(func)
    if flags & FUNC_LIB:
        print hex(func), "FUNC_LIB", GetFunctionName(func)

Python>
0x1a711160 FUNC_LIB _strcpy
0x1a711170 FUNC_LIB _strcat
0x1a711260 FUNC_LIB _memcmp
0x1a711320 FUNC_LIB _memcpy
0x1a711662 FUNC_LIB __onexit
...
0x1a711915 FUNC_LIB _exit
0x1a711926 FUNC_LIB __exit
0x1a711937 FUNC_LIB __cexit
0x1a711946 FUNC_LIB __c_exit
0x1a711955 FUNC_LIB _puts
0x1a7119c0 FUNC_LIB _strcmp
```

## FUNC\_STATIC

This flag is used to identify functions that were compiled as a static function. In C functions are global by default. If the author defines a function as static it can be only accessed by other functions within that file. In a limited way this could be used to aid in understanding how the source code was structured.

## FUNC\_FRAME

This flag indicates the function uses a frame pointer `ebp`. Functions that use frame pointers will typically start with the standard function prologue for setting up the stack frame.

```
.text:1A716697      push    ebp
.text:1A716698      mov     ebp, esp
.text:1A71669A      sub     esp, 5Ch
```

## FUNC\_BOTTOMBP

Similar to `FUNC_FRAME` this flag is used to track the frame pointer. It will identify functions that frame pointers is equal to the stack pointer.

## FUNC\_HIDDEN

Functions with the `FUNC_HIDDEN` flag means they are hidden and will need to be expanded to view. If we were to go to an address of a function that is marked as hidden it would automatically be expanded.

## FUNC\_THUNK

This flag identifies functions that are thunk functions. They are simple functions that jump to another function.

```
.text:1A710606 Process32Next proc near
.text:1A710606      jmp     ds:__imp_Process32Next
.text:1A710606 Process32Next endp
```

It should be noted that a function can consist of multiple flags.

```
0x1a716697 FUNC_LIB
0x1a716697 FUNC_FRAME
0x1a716697 FUNC_HIDDEN
0x1a716697 FUNC_BOTTOMBP
```

# Instructions

Since we know how to work with functions go over how to access their instructions. If we have the address of a function we can use `idautils.FuncItems(ea)` to get a list of all the addresses.

```
Python>dism_addr = list(idautils.FuncItems(here()))
Python>type(dism_addr)
<type 'list'>
Python>print dism_addr
[4573123, 4573126, 4573127, 4573132]
Python>for line in dism_addr: print hex(line),
ida.GetDisasm(line)
0x45c7c3 mov     eax, [ebp-60h]
0x45c7c6 push    eax                ; void *
0x45c7c7 call    w_delete
0x45c7cc retn
```

`idautils.FuncItems(ea)` actually returns an iterator type but is cast to a `list`. The list will contain the start address of each instruction in consecutive order. Now that we have a good knowledge base for looping through segments, functions and instructions let show a useful example. Sometimes when reversing packed code it is useful to only know where dynamic calls happens. A dynamic call would be a call or jump to an operand that is a register such as `call eax` or `jmp edi`.

```
Python>
for func in idautils.Functions():
    flags = ida.GetFunctionFlags(func)
    if flags & FUNC_LIB or flags & FUNC_THUNK:
        continue
    dism_addr = list(idautils.FuncItems(func))
    for line in dism_addr:
        m = ida.GetMnem(line)
        if m == 'call' or m == 'jmp':
            op = ida.GetOpType(line, 0)
            if op == o_reg:
                print "0x%x %s" % (line, ida.GetDisasm(line))
Python>
0x43ebde call    eax                ; VirtualProtect
```

We call `idautils.Functions()` to get a list of all known functions. For each function we retrieve the functions flags by calling `ida.GetFunctionFlags(ea)`. If the function is library code or a thunk function the function is passed. Next we call `idautils.FuncItems(ea)` to get all the addresses within the function. We loop through

the list using a `for` loop. Since we are only interested in `call` and `jmp` instructions we need to get the mnemonic by calling `idc.GetMnem(ea)`. We then use a simple string comparison to check the mnemonic. If the mnemonic is a jump or call we get the operand type by calling `idc.GetOpType(ea, n)`. This function will return an integer that is internally called `op_t.type`. This value can be used to determine if the operand is a register, memory reference, etc. We then check if the `op_t.type` is a register. If so, we print the line. Casting the return of `idautils.FuncItems(ea)` into a `list` is useful because iterators do not have objects such as `len()`. By casting it as a list we could easily get the number of lines or instructions in a function.

```
Python>ea = here()
Python>len(idautils.FuncItems(ea))
Traceback (most recent call last):
  File "<string>", line 1, in <module>
TypeError: object of type 'generator' has no len()
Python>len(list(idautils.FuncItems(ea)))
39
```

In the previous example we used a list that contained all addresses within a function. We looped each entity to access the next instruction. What if we only had an address and wanted to get the next instruction? To move to the next instruction address we can use `idc.NextHead(ea)` and to get the previous instruction address we use `idc.PrevHead(ea)`. These functions will get the start of the next instruction but not the next address. To get the next address we use `idc.NextAddr(ea)` and to get the previous address we use `idc.PrevAddr(ea)`.

```
Python>ea = here()
Python>print hex(ea), idc.GetDisasm(ea)
0x10004f24 call    sub_10004F32
Python>next_instr = idc.NextHead(ea)
Python>print hex(next_instr), idc.GetDisasm(next_instr)
0x10004f29 mov     [esi], eax
Python>prev_instr = idc.PrevHead(ea)
Python>print hex(prev_instr), idc.GetDisasm(prev_instr)
0x10004f1e mov     [esi+98h], eax
Python>print hex(idc.NextAddr(ea))
0x10004f25
Python>print hex(idc.PrevAddr(ea))
0x10004f23
```

# Operands

Operand types are commonly used so it will be beneficial to go over all the types. As previously stated we can use `idc.GetOpType(ea, n)` to get the operand type. `ea` is the address and `n` is the index. There are eight different types of operand types.

`o_void`

If an instruction does not have any operands it will return 0.

```
Python>print hex(ea), idc.GetDisasm(ea)
0xa09166 retn
Python>print idc.GetOpType(ea,0)
0
```

`o_reg`

If an operand is a general register it will return this type. This value is internally represented as 1.

```
Python>print hex(ea), idc.GetDisasm(ea)
0xa09163 pop     edi
Python>print idc.GetOpType(ea,0)
1
```

`o_mem`

If an operand is direct memory reference it will return this type. This value is internally represented as 2. This type is useful for finding references to DATA.

```
Python>print hex(ea), idc.GetDisasm(ea)
0xa05d86 cmp     ds:dword_A152B8, 0
Python>print idc.GetOpType(ea,0)
2
```

`o_phrase`

This operand is returned if the operand consists of a base register and/or an index register.

This value is internally represented as 3.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x1000b8c2 mov     [edi+ecx], eax
Python>print idc.GetOpType(ea,0)
3
```

o\_displ

This operand is returned if the operand consists of registers and a displacement value. The displacement is an integer value such 0x18. It is commonly seen when an instruction accesses values in a structure. Internally it is represented as a value of 4.

```
Python>print hex(ea), idc.GetDisasm(ea)
0xa05dc1 mov     eax, [edi+18h]
Python>print idc.GetOpType(ea,1)
4
```

o\_imm

Operands that are a value such as an integer of 0xC are of this type. Internally it is represented as 5.

```
Python>print hex(ea), idc.GetDisasm(ea)
0xa05da1 add     esp, 0Ch
Python>print idc.GetOpType(ea,1)
5
```

o\_far

This operand is not very common when reversing x86 or x86\_64. It is used to find operands that are accessing immediate far addresses. It is represented internally as 6

o\_near

This operand is not very common when reversing x86 or x86\_64. It is used to find operands that are accessing immediate near addresses. It is represented internally as 7.

## Example

While reversing an executable we might notice that the code keeps referencing recurring displacement values. This is a likely indicator that the code is passing a structure to different functions. go over an example to create a Python dictionary that contains all the displacements as keys and each key will have a list of the addresses. In the code below there will be a new function that has yet to be described. The function is similar to `idc.GetOpType(ea, n)`.

```
import idutils
import idaapi
displace = {}

# for each known function
for func in idutils.Functions():
    flags = idc.GetFunctionFlags(func)
    # skip library & thunk functions
    if flags & FUNC_LIB or flags & FUNC_THUNK:
        continue
    dism_addr = list(idutils.FuncItems(func))
    for curr_addr in dism_addr:
        op = None
        index = None
        # same as idc.GetOpType, just a different way of accessing
        the types
        idaapi.decode_insn(curr_addr)
        if idaapi.cmd.Op1.type == idaapi.o_displ:
            op = 1
        if idaapi.cmd.Op2.type == idaapi.o_displ:
            op = 2
        if op == None:
            continue
        if "bp" in idaapi.tag_remove(idaapi.ua_outop2(curr_addr,
0)) or \
            "bp" in
idaapi.tag_remove(idaapi.ua_outop2(curr_addr, 1)):
            # ebp will return a negative number
            if op == 1:
                index = (~(int(idaapi.cmd.Op1.addr) - 1) &
0xFFFFFFFF)
            else:
                index = (~(int(idaapi.cmd.Op2.addr) - 1) &
0xFFFFFFFF)
            else:
                if op == 1:
                    index = int(idaapi.cmd.Op1.addr)
```

```

        else:
            index = int(idaapi.cmd.Op2.addr)
            # create key for each unique displacement value
            if index:
                if displace.has_key(index) == False:
                    displace[index] = []
                displace[index].append(curr_addr)

```

The start of the code should already look familiar. We use a combination of `idautils.Functions()` and `GetFunctionFlags(ea)` to get all applicable functions while ignoring libraries and thunks. We get each instruction in a function by calling `idautils.FuncItems(ea)`. From here this is where a new function `idaapi.decode_insn(ea)` is called. This function takes the address of instruction we want decoded. Once it is decoded we can access different properties of the instruction by accessing it via `idaapi.cmd`.

```

Python>dir(idaapi.cmd)
['Op1', 'Op2', 'Op3', 'Op4', 'Op5', 'Op6', 'Operands', .....,
'assign', 'auxpref', 'clink', 'clink_ptr', 'copy', 'cs', 'ea',
'flags', 'get_canon_feature', 'get_canon_mnem', 'insnpref', 'ip',
'is_canon_insn', 'is_macro', 'itype', 'segpref', 'size']

```

As we can see from the `dir()` command `idaapi.cmd` has a good amount of attributes. Now back to our example. The operand type is accessed by using `idaapi.cmd.Op1.type`. Please note that the operand index starts at 1 rather than 0 which is different than `idc.GetOpType(ea, n)`. We then check if the operand one or operand two is of `o_displ` type. We use `idaapi.tag_remove(idaapi.ua_outop2(ea, n))` to get a string representation of the operand. It would be shorter and easier to read if we called `idc.GetOpnd(ea, n)`. For example purposes this is a good way to show that there is more than one function to access attributes using IDAPython. If we were to look at the IDAPython source code for `idc.GetOpnd(ea, n)` we would see the lower level approach.

```

def GetOpnd(ea, n):
    """
    Get operand of an instruction

    @param ea: linear address of instruction
    @param n: number of operand:
        0 - the first operand
        1 - the second operand

    @return: the current text representation of operand

```

```

"""
res = idaapi.ua_outop2(ea, n)

if not res:
    return ""
else:
    return idaapi.tag_remove(res)

```

Now back to our example. Since we have the string we need to check if the operand contains the string "bp". This is a quick way to determine if the register bp, ebp or rbp is present in the operand. We check for "bp" because we need to determine if the displacement value is negative or not. To access the displacement value we use `idaapi.cmd.Op1.addr`. This will return a string. Now that we have the address we convert it to an integer, make it positive if needed, and then added it to our dictionary named `displace`. If there is a displacement value that we wanted to search for we could access it using the following for loop.

```

Python>for x in displace[0x130]: print hex(x), GetDisasm(x)
0x10004f12 mov     [esi+130h], eax
0x10004f68 mov     [esi+130h], eax
0x10004fda push    dword ptr [esi+130h] ; hObject
0x10005260 push    dword ptr [esi+130h] ; hObject
0x10005293 push    dword ptr [eax+130h] ; hHandle
0x100056be push    dword ptr [esi+130h] ; hEvent
0x10005ac7 push    dword ptr [esi+130h] ; hEvent

```

0x130 is the displacement value we are interested in. This can be modified to print other displacements.

## Example

Sometimes when reversing a memory dump of an executable the operands are not recognized as an offset.

seg000:00BC1388	push	0Ch
seg000:00BC138A	push	0BC10B8h
seg000:00BC138F	push	[esp+10h+arg_0]
seg000:00BC1393	call	ds:_strnicmp

The second value being pushed is a memory offset. If we were to right click on it and

change it to a data type; we would see the offset to a string. This is okay to do once or twice but after that we might as well automate the process.

```
min = MinEA()
max = MaxEA()
# for each known function
for func in idutils.Functions():
    flags = idc.GetFunctionFlags(func)
    # skip library & thunk functions
    if flags & FUNC_LIB or flags & FUNC_THUNK:
        continue
    dism_addr = list(idutils.FuncItems(func))
    for curr_addr in dism_addr:
        if idc.GetOpType(curr_addr, 0) == 5 and \
            (min < idc.GetOperandValue(curr_addr, 0) < max):
            idc.OpOff(curr_addr, 0, 0)
        if idc.GetOpType(curr_addr, 1) == 5 and \
            (min < idc.GetOperandValue(curr_addr, 1) < max):
            idc.OpOff(curr_addr, 1, 0)
```

After running the above code we would now see the string.

seg000:00BC1388	<b>push</b>	0Ch
seg000:00BC138A	<b>push</b>	offset aNtoskrnl_exe ;
"ntoskrnl.exe"		
seg000:00BC138F	<b>push</b>	[esp+10h+arg_0]
seg000:00BC1393	<b>call</b>	ds:_strnicmp

At the start we get the minimum and maximum address by calling `MinEA()` and `MaxEA()`. We loop through all functions and instructions. For each instruction we check if the operand type is of `o_imm` and is represented internally as the number 5. `o_imm` types are values such as an integer or an offset. Once a value is found we read the value by calling `idc.GetOperandValue(ea, n)`. The value is then checked to see if it is in the range of the minimum and maximum addresses. If so, we use `idc.OpOff(ea, n, base)` to convert the operand to an offset. The first argument `ea` is the address, `n` is the operand index and `base` is the base address. Our example only needs to have a `base` of zero.

## Xrefs

Being able to locate cross-references aka xrefs to data or code is very important. Xrefs are important because they provide locations of where certain data is being used or where a function is being called from. For example what if we wanted to locate the address of where `WriteFile` was called from. Using Xrefs all we would need to do is locate the address of `WriteFile` in the import table and then find all xrefs to it.

```
Python>wf_addr = idc.LocByName("WriteFile")
Python>print hex(wf_addr), idc.GetDisasm(wf_addr)
0x1000e1b8 extrn WriteFile:dword
Python>for addr in idutils.CodeRefsTo(wf_addr, 0):\
    print hex(addr), idc.GetDisasm(addr)
0x10004932 call    ds:WriteFile
0x10005c38 call    ds:WriteFile
0x10007458 call    ds:WriteFile
```

In the first line we get the address of the API `WriteFile` by using `idc.LocByName(str)`. This function will return the address of the API. We print out the address of `WriteFile` and it's string representation. Then loop through all code cross references by calling `idutils.CodeRefsTo(ea, flow)`. It will return an iterator that can be looped through. `ea` is the address that we would like to have cross-referenced to. The argument `flow` is a `bool`. It is used to specify to follow normal code flow or not. Each cross reference to the address is then displayed. A quick note about the use of `idc.LocByName(str)`. All renamed functions and APIs in an IDB can be accessed by calling `idutils.Names()`. This function returns an iterator object which can be looped through to print or access the names. Each named item is a tuple of `(ea, str_name)`.

```
Python>[x for x in Names()]
[(268439552, 'SetEventCreateThread'), (268439615, 'StartAddress'),
(268441102, 'SetSleepClose'),....
```

If we wanted to get where code was referenced from we would use `idutils.CodeRefsFrom(ea, flow)`. For example lets get the address of where `0x10004932` is referenced from.

```
Python>ea = 0x10004932
Python>print hex(ea), idc.GetDisasm(ea)
0x10004932 call    ds:WriteFile
Python>for addr in idutils.CodeRefsFrom(ea, 0):\
    print hex(addr), idc.GetDisasm(addr)
Python>
0x1000e1b8 extrn WriteFile:dword
```

If we review the `idautils.CodeRefsTo(ea, flow)` example we will see the address `0x10004932` is a to address to `WriteFile`. `idautils.CodeRefsTo(ea, flow)` and `idautils.CodeRefsFrom(ea, flow)` are used to search for cross references to and from code. A limitation of using `idautils.CodeRefsTo(ea, flow)` is that APIs that are imported dynamically and then manually renamed will not show up as code cross-references. say we manually rename a dword address to `"RtlCompareMemory"` using `idc.MakeName(ea, name)`.

```
Python>hex(ea)
0xa26c78
Python>idc.MakeName(ea, "RtlCompareMemory")
True
Python>for addr in idautils.CodeRefsTo(ea, 0):\
    print hex(addr), idc.GetDisasm(addr)
```

IDA will not label these APIs as code cross references. A little later we will describe a generic technique to get all cross references. If we wanted to search for cross references to and from data we could use `idautils.DataRefsTo(e)` or `idautils.DataRefsFrom(ea)`.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x1000e3ec db 'vnc32',0
Python>for addr in idautils.DataRefsTo(ea): print hex(addr),
idc.GetDisasm(addr)
0x100038ac push    offset aVnc32          ; "vnc32"
```

`idautils.DataRefsTo(ea)` takes an argument of the address and returns an iterator of all the addresses that cross reference to the data.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x100038ac push    offset aVnc32          ; "vnc32"
Python>for addr in idautils.DataRefsFrom(ea): print hex(addr),
idc.GetDisasm(addr)
0x1000e3ec db 'vnc32',0
```

To do the reverse and show the from address we call `idautils.DataRefsFrom(ea)`, pass the address as an argument. Which returns an iterator of all the addresses that cross reference back to the data. The different usage of code and data can be a little confusing. As previously mentioned lets describe a more generic technique. This approach can be used to get all cross references to an address by calling a single function. We can get all cross references to an address using `idautils.XrefsTo(ea, flags=0)` and get all cross references from an address by calling `idautils.XrefsFrom(ea, flags=0)`.

```

Python>print hex(ea), idc.GetDisasm(ea)
0x1000eee0 unicode 0, <Path>,0
Python>for xref in idutils.XrefsTo(ea, 1):
    print xref.type, idutils.XrefTypeName(xref.type), \
        hex(xref.frm), hex(xref.to), xref.iscode
Python>
1 Data_Offset 0x1000ac0d 0x1000eee0 0
Python>print hex(xref.frm), idc.GetDisasm(xref.frm)
0x1000ac0d push    offset KeyName    ; "Path"

```

The first line displays our address and a string named `<Path>`. We use `idutils.XrefsTo(ea, 1)` to get all cross references to the string. We then use `xref.type` to print the xrefs type value. `idutils.XrefTypeName(xref.type)` is used to print the string representation of this type. There are twelve different documented reference type values. The value can be seen on the left and its corresponding name can be seen below.

```

0  = 'Data_Unknown'
1  = 'Data_Offset'
2  = 'Data_Write'
3  = 'Data_Read'
4  = 'Data_Text'
5  = 'Data_Informational'
16 = 'Code_Far_Call'
17 = 'Code_Near_Call'
18 = 'Code_Far_Jump'
19 = 'Code_Near_Jump'
20 = 'Code_User'
21 = 'Ordinary_Flow'

```

The `xref.frm` prints out the from address and `xref.to` prints out the two address. `xref.iscode` prints if the xref is in a code segment. In the previous example we had the flag of `idutils.XrefsTo(ea, 1)` set to the value 1. If the flag is zero any cross reference will be displayed. say we have the below block of assembly.

```

.text:1000AAF6      jnb     short loc_1000AB02    ; XREF
.text:1000AAF8      mov     eax, [ebx+0Ch]
.text:1000AAFB      mov     ecx, [esi]
.text:1000AAFD      sub     eax, edi
.text:1000AAFF      mov     [edi+ecx], eax
.text:1000AB02
.text:1000AB02 loc_1000AB02:    ; ea is

```

```
here()
.text:1000AB02      mov     byte ptr [ebx], 1
```

We have the cursor at 1000AB02 . This address has a cross reference from 1000AAF6 but it also has second cross reference.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x1000ab02 mov     byte ptr [ebx], 1
Python>for xref in idutils.XrefsTo(ea, 1):
    print xref.type, idutils.XrefTypeName(xref.type), \
          hex(xref.frm), hex(xref.to), xref.iscode
Python>
19 Code_Near_Jump 0x1000aaf6 0x1000ab02 1
Python>for xref in idutils.XrefsTo(ea, 0):
    print xref.type, idutils.XrefTypeName(xref.type), \
          hex(xref.frm), hex(xref.to), xref.iscode
Python>
21 Ordinary_Flow 0x1000aaff 0x1000ab02 1
19 Code_Near_Jump 0x1000aaf6 0x1000ab02 1
```

The second cross reference is from 1000AAFF to 1000AB02 . Cross references do not have to be caused by branch instructions. They can also be caused by normal ordinary code flow. If we set the flag to 1 Ordinary\_Flow reference types will not be added. go back to our RtlCompareMemory example from earlier. We can use idutils.XrefsTo(ea, flow) to get all cross references.

```
Python>hex(ea)
0xa26c78
Python>idc.MakeName(ea, "RtlCompareMemory")
True
Python>for xref in idutils.XrefsTo(ea, 1):
    print xref.type, idutils.XrefTypeName(xref.type), \
          hex(xref.frm), hex(xref.to), xref.iscode
Python>
3 Data_Read 0xa142a3 0xa26c78 0
3 Data_Read 0xa143e8 0xa26c78 0
3 Data_Read 0xa162da 0xa26c78 0
```

Getting all cross references can be a little verbose sometimes.

```
Python>print hex(ea), idc.GetDisasm(ea)
```

```

0xa21138 extrn GetProcessHeap:dword
Python>for xref in idutils.XrefsTo(ea, 1):
    print xref.type, idutils.XrefTypeName(xref.type), \
        hex(xref.frm), hex(xref.to), xref.iscode
Python>
17 Code_Near_Call 0xa143b0 0xa21138 1
17 Code_Near_Call 0xa1bb1b 0xa21138 1
3 Data_Read 0xa143b0 0xa21138 0
3 Data_Read 0xa1bb1b 0xa21138 0
Python>print idc.GetDisasm(0xa143b0)
call    ds:GetProcessHeap

```

The verbosity comes from the `Data_Read` and the `Code_Near` both added to the xrefs. Getting all the addresses and adding them to a set can be useful to slim down on all the addresses.

```

def get_to_xrefs(ea):
    xref_set = set([])
    for xref in idutils.XrefsTo(ea, 1):
        xref_set.add(xref.frm)
    return xref_set

def get_frm_xrefs(ea):
    xref_set = set([])
    for xref in idutils.XrefsFrom(ea, 1):
        xref_set.add(xref.to)
    return xref_set

```

Example of the slim down functions on our `GetProcessHeap` example.

```

Python>print hex(ea), idc.GetDisasm(ea)
0xa21138 extrn GetProcessHeap:dword
Python>get_to_xrefs(ea)
set([10568624, 10599195])
Python>[hex(x) for x in get_to_xrefs(ea)]
['0xa143b0', '0xa1bb1b']

```

## Searching

We have already gone over some basic searches by iterating over all known functions or instructions. This is useful but sometimes we need to search for specific bytes such as `0x55 0x8B 0xEC`. This byte pattern is the classic function prologue `push ebp, mov ebp, esp`. To search for byte or binary patterns we can use `idc.FindBinary(ea, flag, searchstr, radix=16)`. `ea` is the address that we would like to search from the `flag` is the direction or condition. There are a number of different types of flags. The names and values can be seen below.

```
SEARCH_UP = 0
SEARCH_DOWN = 1
SEARCH_NEXT = 2
SEARCH_CASE = 4
SEARCH_REGEX = 8
SEARCH_NOBRK = 16
SEARCH_NOSHOW = 32
SEARCH_UNICODE = 64 **
SEARCH_IDENT = 128 **
SEARCH_BRK = 256 **
** Older versions of IDAPython do not support these
```

Not all of these flags are worth going over but touch upon the most commonly used flags.

- `SEARCH_UP` and `SEARCH_DOWN` are used to select the direction we would like our search to follow.
- `SEARCH_NEXT` is used to get the next found object.
- `SEARCH_CASE` is used to specify case sensitivity.
- `SEARCH_NOSHOW` will not show the search progress.
- `SEARCH_UNICODE` is used to treat all search strings as Unicode.

`searchstr` is the pattern we are search for. The `radix` is used when writing processor modules. This topic is outside of the scope of this book. I would recommend reading Chapter 19 of Chris Eagle's *The IDA Pro Book*. For now the `radix` field can be left blank. go over a quick walk through on finding the function prologue byte patten mentioned earlier.

```
Python>pattern = '55 8B EC'
addr = MinEA()
for x in range(0,5):
    addr = idc.FindBinary(addr, SEARCH_DOWN, pattern);
    if addr != idc.BADADDR:
        print hex(addr), idc.GetDisasm(addr)
Python>
0x401000 push    ebp
0x401000 push    ebp
```

```
0x401000 push    ebp
0x401000 push    ebp
0x401000 push    ebp
```

In the first line we define our search pattern. The search pattern can be in the format of hexadecimal starting with `0x` as in `0x55 0x8B 0xEC` or as bytes appear in IDA's hex view `55 8B EC`. The format `\x55\x8B\xEC` can not be used unless we were using `idc.FindText(ea, flag, y, x, searchstr)`. `MinEA()` is used to get the first address in the executable. We then assign the return of `idc.FindBinary(ea, flag, searchstr, radix=16)` to a variable called `addr`.

When searching it is important to verify that the search did find the pattern. This is tested by comparing `addr` with `idc.BADADDR`. We then print the address and disassembly. Notice how the address did not increment? This is because we did not pass the `SEARCH_NEXT` flag. If this flag is not passed the current address is used to search for the pattern. If the last address contained our byte pattern the search will never increment passed it. Below is the corrected version.

```
Python>pattern = '55 8B EC'
addr = MinEA()
for x in range(0,5):
    addr = idc.FindBinary(addr, SEARCH_DOWN|SEARCH_NEXT,
pattern);
    if addr != idc.BADADDR:
        print hex(addr), idc.GetDisasm(addr)
Python>
0x401040 push    ebp
0x401070 push    ebp
0x4010e0 push    ebp
0x401150 push    ebp
0x4011b0 push    ebp
```

Searching for byte patterns is useful but sometimes we might want to search for strings such as "chrome.dll". We could convert the strings to a hex bytes using `[hex(y) for y in bytearray("chrome.dll")]` but this is a little ugly. Also, if the string is unicode we would have to account for that format. The simplest approach is using `FindText(ea, flag, y, x, searchstr)`. Most of these fields should look familiar because they are the same as `idc.FindBinary`. `ea` is the start address and `flag` is the direction and types to search for. `y` is the number of lines at `ea` to search from and `x` is the coordinate in the line. These fields are typically assigned as `0`. Now search for occurrences of the string "Accept". Any string from the strings window `shift+F12` can be used for this example.

```

Python>cur_addr = MinEA()
end = MaxEA()
while cur_addr < end:
    cur_addr = idc.FindText(cur_addr, SEARCH_DOWN, 0, 0,
"Accept")
    if cur_addr == idc.BADADDR:
        break
    else:
        print hex(cur_addr), idc.GetDisasm(cur_addr)
        cur_addr = idc.NextHead(cur_addr)
Python>
0x40da72 push    offset aAcceptEncoding; "Accept-Encoding:\n"
0x40face push    offset aHttp1_1Accept; " HTTP/1.1\r\nAccept: */*
\r\n "
0x40fadf push    offset aAcceptLanguage; "Accept-Language: ru
\r\n"
...
0x423c00 db  'Accept',0
0x423c14 db  'Accept-Language',0
0x423c24 db  'Accept-Encoding',0
0x423ca4 db  'Accept-Ranges',0

```

We use `MinEA()` to get the minimum address and assign that to a variable named `cur_addr`. This is similarly done again for the maximum address by calling `MaxEA()` and assigning the return to a variable named the `end`. Since we do not know how many occurrences of the string will be present, we need to check that the search continues down and is less than the maximum address. We then assign the return of `idc.FindText` to the current address. Since we will be manually incrementing the address by calling `idc.NextHead(ea)` we do not need the `SEARCH_NEXT` flag. The reason why we manually increment the current address to the following line is because a string can occur multiple times on a single line. This can make it tricky to get the address of the next string.

Along with pattern searching previously described there a couple of functions that can be used to find other types. The naming conventions of the find APIs makes it easy to infer it's overall functionality. Before we discuss finding the different types we firstly go over identifying types by their address. There is a subset of APIs that start with `is` that can be used to determine an address' type. The APIs return a Boolean value of `True` or `False`.

`idc.isCode(f)`

Returns `True` if IDA has marked the address as code.

`idc.isData(f)`

Returns `True` if IDA has marked the address as data.

`idc.isTail(f)`

Returns `True` if IDA has marked the address as tail.

`idc.isUnknown(f)`

Returns `True` if IDA has marked the address as unknown. This type is used when IDA has not identified if the address is code or data.

`idc.isHead(f)`

Returns `True` if IDA has marked the address as head.

The `f` is new to us. Rather than passing an address we first need to get the internal flags representation and then pass it to our `idc.is` set of functions. To get the internal flags we use `idc.GetFlags(ea)`. Now that we have a basics on how the function can be used and the different types lets do a quick example.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x10001000 push    ebp
Python>idc.isCode(idc.GetFlags(ea))
True
```

`idc.FindCode(ea, flag)`

It is used to find the next address that is marked as code. This can be useful if we want to find the end of a block of data. If `ea` is an address that is already marked as code it will return the next address. The `flag` is used as previously described in `idc.FindText`.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x4140e8 dd offset dword_4140EC
Python>addr = idc.FindCode(ea, SEARCH_DOWN|SEARCH_NEXT)
Python>print hex(addr), idc.GetDisasm(addr)
0x41410c push    ebx
```

As we can see `ea` is the address `0x4140e8` of some data. We assign the return of `idc.FindCode(ea, SEARCH_DOWN|SEARCH_NEXT)` to `addr`. Then we print `addr` and it's disassembly. By calling this single function we skipped 36 bytes of data to get the start of a section marked as code.

`idc.FindData(ea, flag)`

It is used exactly as `idc.FindCode` except it will return the start of the next address that is marked as a block of data. If we reverse the previous scenario and start from the address of code and search up to find the start of the data.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x41410c push ebx
Python>addr = idc.FindData(ea, SEARCH_UP|SEARCH_NEXT)
Python>print hex(addr), idc.GetDisasm(addr)
0x4140ec dd 49540E0Eh, 746E6564h, 4570614Dh, 7972746Eh, 8, 1,
4010BCh
```

The only thing that is slightly different than the previous example is the direction of `SEARCH_UP|SEARCH_NEXT` and searching for data.

`idc.FindUnexplored(ea, flag)`

This function is used to find the address of bytes that IDA did not identify as code or data. The `unknown` type will require further manual analysis either visually or through scripting.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x406a05 jge short loc_406A3A
Python>addr = idc.FindUnexplored(ea, SEARCH_DOWN)
Python>print hex(addr), idc.GetDisasm(addr)
0x41b004 db 0DFh ; ?
```

`idc.FindExplored(ea, flag)`

It is used to find an address that IDA identified as code or data.

```
0x41b900 db ? ;
Python>addr = idc.FindExplored(ea, SEARCH_UP)
Python>print hex(addr), idc.GetDisasm(addr)
0x41b5f4 dd ?
```

This might not seem of any real value but if we were to print the cross references of `addr` we would see it is being used.

```
Python>for xref in idautils.XrefsTo(addr, 1):
```

```

        print hex(xref.frm), idc.GetDisasm(xref.frm)
Python>
0x4069c3 mov     eax, dword_41B5F4[ecx*4]

```

idc.FindImmediate(ea, flag, value)

Rather than searching for a type we might want to search for a specific value. say for example that we have a feeling that the code calls `rand` to generate a random number but we can't find the code. If we knew that `rand` uses the value `0x343FD` as a seed we could search for that number.

```

Python>addr = idc.FindImmediate(MinEA(), SEARCH_DOWN, 0x343FD )
Python>addr
[268453092, 0]
Python>print "0x%x %s %x" % (addr[0], idc.GetDisasm(addr[0]),
addr[1] )
0x100044e4 imul     eax, 343FDh 0

```

In the first line we pass the minimum address via `MinEA()`, search down and then search for the value `0x343FD`. Rather than returning an address as shown in the previous Find APIs `idc.FindImmediate` returns a tuple. The first item in the tuple will be the address and second will be the operand. Similar to the return of `idc.GetOpnd` the first operand starts at zero. When we print the address and disassembly we can see the value is the second operand. If we wanted to search for all uses of an immediate value we could do the following.

```

Python>addr = MinEA()
while True:
    addr, operand = idc.FindImmediate(addr,
SEARCH_DOWN|SEARCH_NEXT, 0x7a )
    if addr != BADADDR:
        print hex(addr), idc.GetDisasm(addr), "Operand ", operand
    else:
        break
Python>
0x402434 dd 9, 0FF0Bh, 0Ch, 0FF0Dh, 0Dh, 0FF13h, 13h, 0FF1Bh, 1Bh
Operand 0
0x40acee cmp     eax, 7Ah Operand 1
0x40b943 push    7Ah Operand 0
0x424a91 cmp     eax, 7Ah Operand 1
0x424b3d cmp     eax, 7Ah Operand 1
0x425507 cmp     eax, 7Ah Operand 1

```

Most of the code should look familiar but since we are searching for multiple values we will be using a while loop and the `SEARCH_DOWN|SEARCH_NEXT` flags.

## Selecting Data

Not always will we want to write code that automatically searches for code or data. In some instances we already know the location of the code or data but we want to select it for analysis. In situations like this we might just want to highlight the code and start working with it in IDAPython. To get the boundaries of selected data we can use `idc.SelStart()` to get the start and `idc.SelEnd()` to get the end. say we have the below code selected.

<code>.text:00408E46</code>	<code>push</code>	<code>ebp</code>
<code>.text:00408E47</code>	<code>mov</code>	<code>ebp, esp</code>
<code>.text:00408E49</code>	<code>mov</code>	<code>al, byte ptr dword_42A508</code>
<code>.text:00408E4E</code>	<code>sub</code>	<code>esp, 78h</code>
<code>.text:00408E51</code>	<code>test</code>	<code>al, 10h</code>
<code>.text:00408E53</code>	<code>jz</code>	<code>short loc_408E78</code>
<code>.text:00408E55</code>	<code>lea</code>	<code>eax, [ebp+Data]</code>

We can use the following code to print out the addresses.

```
Python>start = idc.SelStart()
Python>hex(start)
0x408e46
Python>end = idc.SelEnd()
Python>hex(end)
0x408e58
```

We assign the return of `idc.SelStart()` to `start`. This will be the address of the first selected address. We then use the return of `idc.SelEnd()` and assign it to `end`. One thing to note is that `end` is not the last selected address but the start of the next address. If we preferred to make only one API call we could use `idaapi.read_selection()`. It returns a tuple with the first value being a bool if the selection was read, the second being the start address and the last address being the end.

```
Python>Worked, start, end = idaapi.read_selection()
```

```
Python>print Worked, hex(start), hex(end)
True 0x408e46 0x408e58
```

Be cautious when working with 64 bit samples. The base address is not always correct because the selected start address will cause an integer overflow and the leading digit will be incorrect.

## Comments & Renaming

A personal belief of mine is that if I'm not writing I'm not reversing. Adding comments, renaming functions and interacting with the assembly is one of the best ways to understand what the code is doing. Over time some of the interaction becomes redundant. In situations like this it useful to automate the process.

Before we go over some examples we should first discuss the basics of comments and renaming. There are two types of comments. The first one is a regular comment and the second is a repeatable comment. A regular comment appears at address 0041136B as the text regular comment. A repeatable comment can be seen at address 00411372, 00411386 and 00411392. Only the last comment is a comment that was manually entered. The other comments appear when an instruction references an address (such as a branch condition) that contains a repeatable comment.

```
00411365      mov     [ebp+var_214], eax
0041136B      cmp     [ebp+var_214], 0      ; regular comment
00411372      jnz     short loc_411392      ; repeatable
comment
00411374      push    offset sub_4110E0
00411379      call    sub_40D060
0041137E      add     esp, 4
00411381      movzx   edx, al
00411384      test    edx, edx
00411386      jz      short loc_411392      ; repeatable
comment
00411388      mov     dword_436B80, 1
00411392
00411392 loc_411392:
00411392
00411392      mov     dword_436B88, 1      ; repeatable
comment
0041139C      push    offset sub_4112C0
```

To add comments we use `idc.MakeComm(ea, comment)` and for repeatable comments we use `idc.MakeRptCmt(ea, comment)`. `ea` is the address and `comment` is a string we would like added. The below code adds a comment every time an instruction zeroes out a register or value with `XOR`.

```
for func in idutils.Functions():
    flags = idc.GetFunctionFlags(func)
    # skip library & thunk functions
    if flags & FUNC_LIB or flags & FUNC_THUNK:
        continue
    dism_addr = list(idutils.FuncItems(func))
    for ea in dism_addr:
        if idc.GetMnem(ea) == "xor":
            if idc.GetOpnd(ea, 0) == idc.GetOpnd(ea, 1):
                comment = "%s = 0" % (idc.GetOpnd(ea, 0))
                idc.MakeComm(ea, comment)
```

As previously described we loop through all functions by calling `idutils.Functions()` and loop through all the instructions by calling `list(idutils.FuncItems(func))`. We read the mnemonic using `idc.GetMnem(ea)` and check it is equal to `xor`. If so, we verify the operands are equal with `idc.GetOpnd(ea, n)`. If equal, we create a string with the operand and then make add a non-repeatable comment.

```
0040B0F7      xor     al, al                ; al = 0
0040B0F9      jmp     short loc_40B163
```

To add a repeatable comment we would replace `idc.MakeComm(ea, comment)` with `MakeRptCmt(ea, comment)`. This might be a little more useful because we would see references to branches that zero out a value and likely return 0. To get a comments we simple use `GetCommentEx(ea, repeatable)`. `ea` is the address that contains the comment and `repeatable` is a bool of True or False. To get the above comments we would use the following code snippet.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x40b0f7 xor     al, al                ; al = 0
Python>idc.GetCommentEx(ea, False)
al = 0
```

If the comment was repeatable we would replace `idc.GetCommentEx(ea, False)` with `idc.GetCommentEx(ea, True)`. Instructions are not the only field that can have

comments added. Functions can also have comments added. To add function comment we use `idc.SetFunctionCmt(ea, cmt, repeatable)` and to get a function comment we call `idc.GetFunctionCmt(ea, repeatable)`. `ea` can be any address that is within the boundaries of the start and end of the function. `cmt` is the string comment we would like to add and `repeatable` is a boolean value if we want the comment to be repeatable or not. This can be represented either 0 or false for the comment not being repeatable or 1 or True for the comment to be repeatable. Having the function as repeatable will add a comment for when the comment is being called.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x401040 push    ebp
Python>idc.GetFunctionName(ea)
sub_401040
Python>idc.SetFunctionCmt(ea, "check out later", 1)
True
```

We print the address, disassembly and function name in the first couple of lines. We then use `idc.SetFunctionCmt(ea, comment, repeatable)` to set a repeatable comment of "check out later". If we look at the start of the function we will see our comment.

```
00401040 ; check out later
00401040 ; Attributes: bp-based frame
00401040
00401040 sub_401040 proc near
00401040
00401040 var_4      = dword ptr -4
00401040 arg_0      = dword ptr  8
00401040
00401040          push    ebp
00401041          mov     ebp, esp
00401043          push    ecx
00401044          push    723EB0D5h
```

Since the comment is repeatable, when there is a cross-reference to the function we will see the comment. This is a great place to add reminders or notes about a function.

```
00401C07          push    ecx
00401C08          call     sub_401040      ; check out later
00401C0D          add     esp, 4
```

Renaming functions and addresses is a commonly automated task, especially when dealing

with position independent code (PIC), packers or wrapper functions. The reason why this is common in PIC or unpacked code is because the import table might not be present in the dump. In the case of wrapper functions the full function simply calls an API.

```
10005B3E sub_10005B3E proc near
10005B3E
10005B3E dwBytes    = dword ptr  8
10005B3E
10005B3E      push     ebp
10005B3F      mov      ebp, esp
10005B41      push     [ebp+dwBytes]      ; dwBytes
10005B44      push     8                  ; dwFlags
10005B46      push     hHeap             ; hHeap
10005B4C      call     ds:HeapAlloc
10005B52      pop      ebp
10005B53      retn
10005B53 sub_10005B3E endp
```

In the above code the function could be called `w_HeapAlloc`. The `w_` is short for wrapper. To rename an address we can use the function `idc.MakeName(ea, name)`. `ea` is the address and `name` is the string name such as `"w_HeapAlloc"`. To rename a function `ea` needs to be the first address of the function. To rename the function of our `HeapAlloc` wrapper we would use the following code.

```
Python>print hex(ea), idc.GetDisasm(ea)
0x10005b3e push     ebp
Python>idc.MakeName(ea, "w_HeapAlloc")
True
```

`ea` is the first address in the function and `name` is `"w_HeapAlloc"`.

```
10005B3E w_HeapAlloc proc near
10005B3E
10005B3E dwBytes    = dword ptr  8
10005B3E
10005B3E      push     ebp
10005B3F      mov      ebp, esp
10005B41      push     [ebp+dwBytes]      ; dwBytes
10005B44      push     8                  ; dwFlags
10005B46      push     hHeap             ; hHeap
10005B4C      call     ds:HeapAlloc
10005B52      pop      ebp
```

```
10005B53          retn
10005B53 w_HeapAlloc endp
```

Above we can see the function has been renamed. To confirm it has been renamed we can use `idc.GetFunctionName(ea)` to print the new function's name.

```
Python>idc.GetFunctionName(ea)
w_HeapAlloc
```

Now that we have a good basis of knowledge, show an example of how we can use what we have learned so far to automate the naming of wrapper functions. Please see the inline comments to get an idea about the logic.

```
import idutils

def rename_wrapper(name, func_addr):
    if idc.MakeNameEx(func_addr, name, SN_NOWARN):
        print "Function at 0x%x renamed %s" %( func_addr
, idc.GetFunctionName(func))
    else:
        print "Rename at 0x%x failed. Function %s is being used."
% (func_addr, name)
    return

def check_for_wrapper(func):
    flags = idc.GetFunctionFlags(func)
    # skip library & thunk functions
    if flags & FUNC_LIB or flags & FUNC_THUNK:
        return
    dism_addr = list(idutils.FuncItems(func))
    # get length of the function
    func_length = len(dism_addr)
    # if over 32 lines of instruction return
    if func_length > 0x20:
        return
    func_call = 0
    instr_cmp = 0
    op = None
    op_addr = None
    op_type = None
    # for each instruction in the function
    for ea in dism_addr:
        m = idc.GetMnem(ea)
```

```

    if m == 'call' or m == 'jmp':
        if m == 'jmp':
            temp = idc.GetOperandValue(ea, 0)
            # ignore jump conditions within the function
boundaries
            if temp in dism_addr:
                continue
            func_call += 1
            # wrappers should not contain multiple function calls
            if func_call == 2:
                return
            op_addr = idc.GetOperandValue(ea, 0)
            op_type = idc.GetOpType(ea, 0)
        elif m == 'cmp' or m == 'test':
            # wrappers functions should not contain much logic.
            instr_cmp += 1
            if instr_cmp == 3:
                return
        else:
            continue
    # all instructions in the function have been analyzed
    if op_addr == None:
        return
    name = idc.Name(op_addr)
    # skip mangled function names
    if "[" in name or "$" in name or "?" in name or "@" in name
or name == "":
        return
    name = "w_" + name
    if op_type == 7:
        if idc.GetFunctionFlags(op_addr) & FUNC_THUNK:
            rename_wrapper(name, func)
            return
    if op_type == 2 or op_type == 6:
        rename_wrapper(name, func)
        return

for func in idutils.Functions():
    check_for_wrapper(func)

```

## Example Output

```

Function at 0xa14040 renamed w_HeapFree
Function at 0xa14060 renamed w_HeapAlloc

```

```
Function at 0xa14300 renamed w_HeapReAlloc
Rename at 0xa14330 failed. Function w_HeapAlloc is being used.
Rename at 0xa14360 failed. Function w_HeapFree is being used.
Function at 0xa1b040 renamed w_RtlZeroMemory
```

Most of the code should be familiar. One notable difference is the use of `idc.MakeNameEx(ea, name, flag)` from `rename_wrapper`. We use this function because `idc.MakeName` will throw a warning dialogue if the function name is already in use. By passing a flag value of `SN_NOWARN` or 256 we avoid the dialogue box. We could apply some logic to rename the function to `w_HeapFree_1` but for brevity we will leave that out.

## Accessing Raw Data

Being able to access raw data is essential when reverse engineering. Raw data is the binary representation of the code or data. We can see the raw data or bytes of the instructions on the left side following the address.

00A14380 8B 0D 0C 6D A2 00	<b>mov</b>	ecx, hHeap
00A14386 50	<b>push</b>	eax
00A14387 6A 08	<b>push</b>	8
00A14389 51	<b>push</b>	ecx
00A1438A FF 15 30 11 A2 00	<b>call</b>	ds:HeapAlloc
00A14390 C3	<b>retn</b>	

To access the data we first need to decide on the unit size. The naming convention of the APIs used to access data is the unit size. To access a byte we would call `idc.Byte(ea)` or to access a word we would call `idc.Word(ea)`, etc.

- `idc.Byte(ea)`
- `idc.Word(ea)`
- `idc.Dword(ea)`
- `idc.Qword(ea)`
- `idc.GetFloat(ea)`
- `idc.GetDouble(ea)`

If the cursor was at `00A14380` in the assembly from above we would have the following output.

```
Python>print hex(ea), idc.GetDisasm(ea)
```

```

0xa14380 mov     ecx, hHeap
Python>hex( idc.Byte(ea) )
0x8b
Python>hex( idc.Word(ea) )
0xd8b
Python>hex( idc.Dword(ea) )
0x6d0c0d8b
Python>hex( idc.Qword(ea) )
0x6a5000a26d0c0d8bL
Python>idc.GetFloat(ea) # Example not a float value
2.70901711372e+27
Python>idc.GetDouble(ea)
1.25430839165e+204

```

When writing decoders it is not always useful to get a single byte or read a dword but to read a block of raw data. To read a specified size of bytes at an address we can use `idc.GetManyBytes(ea, size, use_dbg=False)`. The last argument is optional and is only needed if we wanted the debuggers memory.

```

Python>for byte in idc.GetManyBytes(ea, 6):
    print "0x%X" % ord(byte),
0x8B 0xD 0xC 0x6D 0xA2 0x0

```

It should be noted that `idc.GetManyBytes(ea, size)` returns the char representation of the byte(s). This is different than `idc.Word(ea)` or `idc.Qword(ea)` which returns an integer.

## Patching

Sometimes when reversing malware the sample will have strings that are encoded. This is done to slow down the analysis process and to thwart using a strings viewer to recover indicators. In situations like this patching the IDB is useful. We could rename the address but renaming is limited. This is due to the naming convention restrictions. To patch an address with a value we can use the following functions.

- `idc.PatchByte(ea, value)`
- `idc.PatchWord(ea, value)`
- `idc.PatchDword(ea, value)`

`ea` is the address and `value` is the integer value that we would like to patch the IDB with.

The size of the value needs to match the size specified by the function name we choose. say for example that we found the following encoded strings.

```
.data:1001ED3C aGcquEUdg_bUfuD db 'gcqu^E]~UDG_B[uFU^DC',0
.data:1001ED51                                align 8
.data:1001ED58 aGcqs_cuufuD  db 'gcqs\_CUuFU^D',0
.data:1001ED66                                align 4
.data:1001ED68 aWud@uubQU   db 'WUD@UUB^Q]U',0
.data:1001ED74                                align 8
```

During our analysis we were able to identify the decoder function.

```
100012A0      push    esi
100012A1      mov     esi, [esp+4+_size]
100012A5      xor     eax, eax
100012A7      test    esi, esi
100012A9      jle     short _ret
100012AB      mov     dl, [esp+4+_key]      ; assign key
100012AF      mov     ecx, [esp+4+_string]
100012B3      push    ebx
100012B4
100012B4 _loop:                                ;
100012B4      mov     bl, [eax+ecx]
100012B7      xor     bl, dl              ; data ^ key
100012B9      mov     [eax+ecx], bl      ; save off byte
100012BC      inc     eax                ; index/count
100012BD      cmp     eax, esi
100012BF      jl      short _loop
100012C1      pop     ebx
100012C2
100012C2 _ret:                                ;
100012C2      pop     esi
100012C3      retn
```

The function is a standard XOR decoder function with arguments of size, key and a decoded buffer.

```
Python>start = idc.SelStart()
Python>end = idc.SelEnd()
Python>print hex(start)
0x1001ed3c
Python>print hex(end)
```

```

0x1001ed50
Python>def xor(size, key, buff):
    for index in range(0,size):
        cur_addr = buff + index
        temp = idc.Byte( cur_addr ) ^ key
        idc.PatchByte(cur_addr, temp)

Python>
Python>xor(end - start, 0x30, start)
Python>idc.GetString(start)
WSAEnumNetworkEvents

```

We select the highlighted data address start and end using `idc.SelStart()` and `idc.SelEnd()`. Then we have a function that reads the byte by calling `idc.Byte(ea)`, XOR the byte with key passed to the function and then patch the byte by calling `idc.PatchByte(ea, value)`.

## Input and Output

Importing and exporting files into IDAPython can be useful when we do not know the file path or when we do not know where the user wants to save their data. To import or save a file by name we use `AskFile(forsave, mask, prompt)`. `forsave` can be a value of `0` if we want to open a dialog box or `1` if we want to open the save dialog box. `mask` is the file extension or pattern. If we want to open only `.dll` files we would use a mask of `"*.dll"` and `prompt` is the title of the window. A good example of input and output and selecting data is the following `IO_DATA` class.

```

import sys
import idaapi

class IO_DATA():
    def __init__(self):
        self.start = SelStart()
        self.end = SelEnd()
        self.buffer = ''
        self.origLen = None
        self.status = True
        self.run()

    def checkBounds(self):
        if self.start is BADADDR or self.end is BADADDR:

```

```

        self.status = False

    def getData(self):
        '''get data between start and end put them into
object.buffer'''
        self.ogLen = self.end - self.start
        self.buffer = ''
        try:
            for byte in idc.GetManyBytes(self.start, self.ogLen):
                self.buffer = self.buffer + byte
        except:
            self.status = False
        return

    def run(self):
        '''basically main'''
        self.checkBounds()
        if self.status == False:
            sys.stdout.write('ERROR: Please select valid data\n')
            return
        self.getData()

    def patch(self, temp = None):
        '''patch idb with data in object.buffer'''
        if temp != None:
            self.buffer = temp
            for index, byte in enumerate(self.buffer):
                idc.PatchByte(self.start+index, ord(byte))

    def importb(self):
        '''import file to save to buffer'''
        fileName = idc.AsFile(0, ".*", 'Import File')
        try:
            self.buffer = open(fileName, 'rb').read()
        except:
            sys.stdout.write('ERROR: Cannot access file')

    def export(self):
        '''save the selected buffer to a file'''
        exportFile = idc.AsFile(1, ".*", 'Export Buffer')
        f = open(exportFile, 'wb')
        f.write(self.buffer)
        f.close()

    def stats(self):

```

```
print "start: %s" % hex(self.start)
print "end:   %s" % hex(self.end)
print "len:   %s" % hex(len(self.buffer))
```

With this class data can be selected saved to a buffer and then stored to a file. This is useful for encoded or encrypted data in an IDB. We can use `IO_DATA` to select the data decode the buffer in Python and then patch the IDB. Example of how to use the `IO_DATA` class.

```
Python> f = IO_DATA()
Python> f.stats()
start: 0x401528
end:   0x401549
len:   0x21
```

Rather than explaining each line of the code it would be useful for the reader to go over the functions one by one and see how they work. The below bullet points explain each variable and what the functions does. `obj` is whatever variable we assign the class. `f` is the `obj` in `f = IO_DATA()`.

- `obj.start`
  - contains the address of the start of the selected offset
- `.obj.end`
  - contains the address of the end of the selected offset.
- `obj.buffer`
  - contains the binary data.
- `obj.ogLen`
  - contains the size of the buffer.
- `obj.getData()`
  - copies the binary data between `obj.start` and `obj.end` to `obj.buffer` `obj.run()` the selected data is copied to the buffer in a binary format
- `obj.patch()`
  - patch the IDB at `obj.start` with the data in the `obj.buffer`.
- `obj.patch(d)`
  - patch the IDB at `obj.start` with the argument data.
- `obj.importb()`
  - opens a file and saves the data in

- `obj.buffer.export()`
  - exports the data in `obj.buffer` to a save as file.
- `obj.stats()`
  - print hex of `obj.start`, `obj.end` and `obj.buffer length`.

## Intel Pin Logger

Pin is a dynamic binary instrumentation framework for the IA-32 and x86-64. Combining the dynamic analysis results of PIN with the static analysis of IDA makes it a powerful mix. A hurdle for combining IDA and Pin is the initial setup and running of Pin. The below steps are the 30 second (minus downloads) guide to installing, executing a Pintool that traces an executable and adds the executed addresses to an IDB.

Notes about steps

- \* Pre-install Visual Studio 2010 (vc10) or 2012 (vc11)
  - \* If executing malware **do** steps 1,2,6,7,8,9,10 & 11 in an analysis machine
1. Download PIN
    - \* **https://software.intel.com/en-us/articles/pintool-downloads**
    - \* Compiler Kit is **for version** of Visual Studio you are **using**.
  2. Unzip pin **to** the root dir and **rename** the **folder to "pin"**
    - \* example path C:\pin\
    - \* There is a known but that Pin will not always parse the arguments correctly **if** there is spacing in the **file** path
  3. Open the following **file** in Visual Studio
    - \* C:\pin\source\tools\MyPinTool\MyPinTool.sln
      - This **file** contains all the needed setting **for** Visual Studio.
      - Useful **to** back up and reuse the **directory** when starting **new** pintools.
  4. Open the below **file**, **then** cut and paste the code **into** MyPinTool.cpp (currently opened in Visual Studio)
    - \* C:\pin\source\tools\ManualExamples\itrace.cpp
      - This **directory** along with ../SimpleExamples is very useful **for** example code.
  5. Build Solution (F7)
  6. Copy traceme.exe **to** C:\pin
  7. Copy compiled MyPinTool.dll **to** C:\pin
    - \* path C:\pin\source\tools\MyPinTool\Debug\MyPinTool.dll

8. Open a **command line and set the working dir to C:\pin**
9. Execute the following **command**
  - \* `pin -t traceme.exe -- MyPinTool.dll`
    - `"-t"` = name of **file to** be analyzed
    - `"-- MyPinTool.dll"` = specifies that pin is **to** use the following pintool/dll
10. While pin is executing **open** traceme.exe in IDA.
11. Once pin has completed (**command line will have returned**)  
**execute the following in IDAPython**
  - \* The pin output (itrace.out) must be in the working dir of the IDB. \

itrace.cpp is a pintool that prints the EIPs of every instruction executed to itrace.out. The data will look like the following output.

```
00401500
00401506
00401520
00401526
00401549
0040154F
0040155E
00401564
0040156A
```

After the pintools has executed we can run the following IDAPython code to add comments to all the executed addresses. The output file `itrace.out` will need to be in the working directory of the IDB.

```
f = open('itrace.out', 'r')
lines = f.readlines()

for y in lines:
    y = int(y,16)
    idc.SetColor(y, CIC_ITEM, 0xffffffff)
    com = idc.GetCommentEx(y,0)
    if com == None or 'count' not in com:
        idc.MakeComm(y, "count:1")
    else:
        try:
            count = int(com.split(':')[1],16)
        except:
            print hex(y)
```

```

        tmp = "count:0x%x" % (count + 1)
        idc.MakeComm(y, tmp)
    f.close()

```

We first open up `itrace.out` and read all lines into a list. We then iterate over each line in the list. Since the address in the output file was in hexadecimal string format we need to convert it into an integer.

```

.text:00401500 loc_401500:                                ; CODE
XREF: sub_4013E0+106j
.text:00401500          cmp     ebx, 457F4C6Ah           ;
count:0x16
.text:00401506          ja      short loc_401520           ;
count:0x16
.text:00401508          cmp     ebx, 1857B5C5h           ; count:1
.text:0040150E          jnz     short loc_4014E0           ; count:1
.text:00401510          mov     ebx, 80012FB8h           ; count:1
.text:00401515          jmp     short loc_4014E0           ; count:1
.text:00401515 ; -----
-----

.text:00401517          align 10h
.text:00401520
.text:00401520 loc_401520:                                ; CODE
XREF: sub_4013E0+126j
.text:00401520          cmp     ebx, 4CC5E06Fh           ;
count:0x15
.text:00401526          ja      short loc_401549           ;
count:0x15

```

## Batch File Generation

Sometimes it can be useful to create IDBs or ASMs for all the files in a directory. This can help save time when analyzing a set of samples that are part of the same family of malware. It's much easier to do batch file generation than doing it manually on a large set. To do batch analysis we will need to pass the `-B` argument to the text `idaw.exe`. The below code can be copied to the directory that contains all the files we would like to generate files for.

```

import os

```

```

import subprocess
import glob
paths = glob.glob("*")
ida_path = os.path.join(os.environ['PROGRAMFILES'], "IDA",
"idadaw.exe")

for file_path in paths:
    if file_path.endswith(".py"):
        continue
    subprocess.call([ida_path, "-B", file_path])

```

We use `glob.glob("*")` to get a list of all files in the directory. The argument can be modified if we wanted to only select a certain regular expression pattern or file type. If we wanted to only get files with a `.exe` extension we would use `glob.glob("*.exe")`. `os.path.join(os.environ['PROGRAMFILES'], "IDA", "idadaw.exe")` is used to get the path to `idadaw.exe`. Some versions of IDA have a folder name with the version number present. If this is the case the argument `"IDA"` will need to be modified to the folder name. Also, the whole command might have to be modified if we choose to use a non-standard install location for IDA. For now let's assume the install path for IDA is `C:\Program Files\IDA`. After we found the path we loop through all the files in the directory that do not contain a `.py` extension and then pass them to IDA. For an individual file it would look like `C:\Program Files\IDA\idadaw.exe -B bad_file.exe`. Once ran it would generate an ASM and IDB for the file. All files will be written in the working directory. An example output can be seen below.

```
C:\injected>dir
```

```

0?/**/_---- 09:30 AM <DIR> .
0?/**/_---- 09:30 AM <DIR> ..
0?/**/_---- 10:48 AM      167,936 bad_file.exe
0?/**/_---- 09:29 AM      270 batch_analysis.py
0?/**/_---- 06:55 PM      104,889 injected.dll

```

```
C:\injected>python batch_analysis.py
```

```
Thank you for using IDA. Have a nice day!
```

```
C:\injected>dir
```

```

0?/**/_---- 09:30 AM <DIR> .
0?/**/_---- 09:30 AM <DIR> ..
0?/**/_---- 09:30 AM      506,142 bad_file.asm
0?/**/_---- 10:48 AM      167,936 bad_file.exe

```

```
0?/**/_---- 09:30 AM 1,884,601 bad_file.idb
0?/**/_---- 09:29 AM 270 batch_analysis.py
0?/**/_---- 09:30 AM 682,602 injected.asm
0?/**/_---- 06:55 PM 104,889 injected.dll
0?/**/_---- 09:30 AM 1,384,765 injected.idb
```

bad\_file.asm, bad\_file.idb, injected.asm and injected.idb were generated files.

## Executing Scripts

IDAPython scripts can be executed from the command line. We can use the following code to count each instruction in the IDB and then write it to a file named `instru_count.txt`.

```
import idc
import idaapi
import idutils

idaapi.autoWait()

count = 0
for func in idutils.Functions():
    # Ignore Library Code
    flags = idc.GetFunctionFlags(func)
    if flags & FUNC_LIB:
        continue
    for instru in idutils.FuncItems(func):
        count += 1

f = open("instru_count.txt", 'w')
print_me = "Instruction Count is %d" % (count)
f.write(print_me)
f.close()

idc.Exit(0)
```

From a command line perspective the two most important functions are `idaapi.autoWait()` and `idc.Exit(0)`. When IDA opens a file it is important to wait for the analysis to complete. This allows IDA to populate all functions, structures, or other values that are based on IDA's analysis engine. To wait for the analysis to complete we call

`idaapi.autoWait()` . It will wait/pause until IDA is completed with its analysis. Once the analysis is completed it will return control back to the script. It is important to execute this at the beginning of the script before we call any IDAPython functions that rely on the analysis to be completed. Once our script has executed we will need to call `idc.Exit(0)` . This will stop execution of our script, close out the database and return to the caller of the script. If not our IDB would not be closed properly.

If we wanted to execute the IDAPython to count all lines we IDB we would execute the following command line.

```
C:\Cridix\idbs>"C:\Program Files (x86)\IDA 6.3\idaw.exe" -A -Scount.py cur-analysis.idb
```

`-A` is for Autonomous mode and `-S` signals for IDA to run a script on the IDB once it has opened. In the working directory we would see a file named `instru_count.txt` that contained a count of all instructions.

## Closing

I hope you gained some knowledge on how to use IDAPython or a trick to solve an issue you are working on. If you have any questions, comments or feedback please send me an email. I plan to keep editing the book. Please not the version number and check it out again in the future. Cheers.
